A THERMAL PROCESSING CHAMBER AND A METHOD OF THERMALLY  
PROCESSING PRODUCTS

Field of the Invention

5 The present invention relates to thermal processing of items in a continuous process, especially food products. The invention relates to a chamber and a method for heating or freezing food products by a combination between thermal convection between a conveyor belt and the product and thermal convection between a cooling or heating medium and the product. The combination provides a better product quality and a higher capacity of  
10 the chamber.

Description of the Prior Art

Devices and methods for continuously freezing or heating food products e.g. for form freezing the food products exist. Known devices typically have conveying means for  
15 conveying the food products through either a heating or a freezing process. The conveying means are typically provided as conveyor belts with an open structure allowing either a cooling or a heating medium such as air to pass through the belt. The belts therefore have conveying surfaces which are non-uniform or rough and which typically causes unwanted structures in the food products as they are either heated or frozen while  
20 being supported on the surface. Furthermore the non-uniformity gives a poor thermal convection from the surface of the conveyor belt to the food products and therefore the thermal efficiency of the devices is relatively low.

When sensitive or delicate food products, such as fish fillets are individually frozen, it is  
25 necessary that the products obtain a stiff outer shape before the product is being handled further, otherwise the value of the product may be lowered. It is therefore essential that the form freezing of the products is completed in one process. In order to ensure the form stability the known tunnel freezers or IQF (Individual quick freezer) installations have relatively long form freezing conveyor belts and therefore the known freezers take up  
30 relatively much space. The same problem applies for devices for continuous heating such as for conveyor ovens.

The known devices typically use conveyer belts wherein a cooling or a heating medium is blown onto the food items either from the side of the belt or from above the belt. Sufficient cooling or heating is achieved by extending the length of the conveyer belts and thereby the size of the chamber. This can be a problem e.g. when the chamber is installed in  
5 ships or in other places with limited space.

### Description of the Invention

It is an object of the present invention to provide a method and a device for continuously processing sensitive food products wherein the efficiency of the processing is improved so  
10 that the quality of the product can be improved with the use of less space for the device.

According to the object the present invention relates to a thermal processing chamber for processing individual product items, said processing chamber comprising:

- sub  
B2 >
- 15 - a conveyor for conveying the product items in the chamber, said conveyor comprising:
    - a conveyor belt forming an endless loop with a processing part and an idling part, the conveyor belt comprising a plurality of thermal conductive elements, each of the elements being adapted to obtain a first orientation in the processing part of the loop  
20 and adapted to obtain a second orientation in the idling part of the loop, the first orientation providing a substantially plan and continuous surface for supporting the product items across at least a number of the elements, and
    - power driven means for advancing the conveyor belt,
  - 25 wherein the thermal processing of the product items is performed by a thermal convection from the elements to the product items.

The power driven means could be regular AC/DC motors with a control system adapted for controlling the position and speed of the conveyor belt. The control system could be  
30 integrated in an industrial PC, which could also be used for the control of the chamber in general, e.g. for the control of the temperature of the chamber or for the control of the processing of the product items.

The chamber may further have means for providing a thermal media to the chamber. The  
35 thermal media could be a gas such as plain air, which is either relatively hot or cold.

The second orientation of the elements could preferably be adapted so that a passage is provided between the elements. This will allow the cold or hot air to flow between the elements and thereby ensure a good distribution of the cold or hot medium in the

5 chamber. At the same time it will allow the medium to cool the elements down or heat them up before they re-enter the processing part of the loop. Preferably the second orientation is adjustable so that the size of the passage can be adjusted, e.g. so that the amount of gas flowing between the elements can be controlled.

10 The thermal conductive elements could be parallel arranged elongated beams having a wing formed cross sectional shape. By arranging each of the beams pivotally around a longitudinal centre axis of the beams, the first orientation of the beams may provide a flat and continued surface across a number of the beams. The second orientation of the beams may provide an open structure with good conditions for the flow of the medium  
15 between the beams.

Sub 33  
The thermal processing of the product items is preferably performed as a combination of a first thermal convection from the elements to the product items and a second thermal convection from the thermal media to the product items.

20

The elements could be thermally influenced by a thermal convection from the thermal media to the elements or the thermal media could be influenced by a thermal convection from the element. As an example the elements could be either cooled down or heated up with cold or hot air flowing in between the elements or the air flowing in between the

25 elements could be either heated or cooled down by the elements. The one or the other situation could be selected based upon which heating or cooling procedure that would be beneficial for a specific case. In a regular cooling process it would make most sense to let the elements be cooled down with cold air produced in a regular cooling element, e.g. comprising a compressor and an evaporator. In a regular heating process on the other  
30 hand, it may make more sense to let the air be heated as it passes the elements, which are heated, from internal electric heating elements.

According to one embodiment of the invention the thermal processing is freezing of the product items and accordingly the thermal media is a cooling media, which could be selected from a group comprising:

- 5 - plain air,
- CO<sub>2</sub> and
- nitrogen.

The elements could also cooled electrically, e.g. by internal thermoelectric elements.

10

According to another embodiment of the invention the thermal processing is heating and accordingly the thermal media is heated gas such as heated air. The air could be heated in a heat exchanger or the air could be heated by the elements, which again could be heated by internal electric heating elements.

15

Preferably the elements are made from a material with a good thermal conductivity such as aluminium. It has been found that a conductivity between 30 W/(K\*m) and 230 W/(K\*m), such as between 209 W/(K\*m) and 229 W/(K\*m) is preferred in order to obtain an efficient cooling or heating of the product items positioned on the elements. W is the  
20 conducted energy, K is degrees Kelvin and m is the length of the material.

The elements could be coated with a material with a low surface friction for the working temperature. As an example the elements could be coated with PTFE (Teflon™) or a similar plastic material. The coating enables the products to fall off the conveyor at the  
25 end of the processing part of the loop, and not stick to the surface of the elements after either a freezing of the products or after a heating of the products. The coating could further protect the elements from corroding. Preferably the elements or the beams are made from deep drawn aluminium profiles which after a chemical sintering is coated with Teflon™.

30

The elements could be adapted to rotate from the first orientation to the second orientation upon movement of the elements in the endless loop from the processing part to the idling part of the loop. The rotation could be caused by gravity in that the elements or beams simply falls from the first orientation around a pivotal hinge into the second  
35 orientation. The elements could then be adapted to rotate back from the second

orientation to the first orientation upon movement of the element in the endless loop from the idling part to the processing part of the loop. The rotation could again be caused by gravity in that the elements and the beams are rotating as they are raised vertically in a circular movement, e.g. around a support or driving wheel of the conveyor. The rotation of  
5 the elements or beams could be stopped in the second orientation wherein the elements or beams are supported, e.g. by the succeeding element or beam in the loop.

Sub  
BS  
10 The thermal chamber may be provided with a number of additional conveyors. The additional conveyors could be provided with belts having a partly open surface towards the thermal media. As an example the belts can be regular plastic belts with a 20, 30 or even 40 percent open structure allowing the thermal media to path through the belts. Such belts would not support thermal convection directly from the belt to the product items but would support the thermal media to flow through the belt and therefore support the convection from the thermal media to the product. The convection e.g. from air to the  
15 product would not be as effective as convection directly from a belt to a product fully supported on the surface of the belt. Still the convection is relatively effective in the case the products are not lying firmly against the surface of the belt anyway and that would typically be the case after the products have been thrown from one belt to another. The plastic belts or similar regular belts can be used e.g. to full freeze the products by  
20 convection between the air and the products.

According to a preferred embodiment of the invention the product items are food items such as fish, meat, cake, bread etc. Accordingly the materials selected for the chamber should be adapted for the purpose of hygienic treatment. Typically the extensive use of  
25 non-corrosive materials such as stainless steel and plastic would be preferred.

Sub  
BS  
30 According to another aspect the invention relates to a method of thermally processing product items in a thermal processing chamber provided with a thermal media, said method comprising the steps of:

- conveying the product items through the chamber on a plurality of thermally conductive elements,
- thermally processing the product by providing a thermal convection from the elements to the product items, and

- simultaneously providing a thermal convection from the thermal media to the product items.

## 5 Detailed description of the invention

A preferred embodiment of the invention adapted for continuously freezing food products, will now be described in details with reference to the drawing in which:

10 Fig. 1 shows a processing chamber according to the present invention,

Fig. 2 shows a processing chamber with an in-feed area and a discharge area, seen from the side,

15 Fig. 3 shows a detailed view of a conveyor belt for a form freezing conveyor,

Fig. 4 shows the view of Fig. 3 including indication of a stream of air flowing through the conveyor belt, and

20 Fig. 5 shows a view of the conveyor belt of Figs. 3 and 4 with an in-feed unit.

The processing chamber is used for freezing the food products individually. The products may be fish fillets or similar pieces of meat and they are frozen individually so that they keep their shape and don't stick together. By individually freezing the items it is possible to  
 25 increase the value of the products and to maximise the values added in the production process.

sub  
B4  
30 The food products are cooled partially by means of convection between a form freezing conveyor belt and the food and partly by means of convection between cold air in the cooling chamber and the food. The temperature in the cooling chamber is approximately minus 38 degrees Celsius, which gives a fast and efficient cooling.

By means of a faster cooling of the products, the time period in which the products are exposed to a strong stream of cooling air is shortened. Therefore the frozen products

The evaporator is divided into a lower and an upper part 9, 10. The evaporator cools the chamber, e.g. by evaporation of CFC gases or by ammonia compressed by a compressor.

The ventilator 11 with the electric motor 12 is adapted for bringing cold air from the evaporator to the conveyor belts. The isolator 13 isolates the chamber from the ambience by counteracting airflow in and out of the chamber. The inlet to the chamber is also provided with an isolator 15.

5

The doors 16 and 17 are as mentioned before provided for inspection and maintenance of the chamber.

Referring to Fig. 3 the form freezing conveyor belts are made from a plurality of elongated  
10 beams 18 connected in an endless belt by means of stainless steel chains 19. The steel chains may be of a regular type but according to a preferred embodiment, bolts 24 are inserted into holes in the end of each of the chain links and thus connect the links of the chain. The bolts are screwed into the elongated beams and thus simultaneously connect the individual links of the chain and connect the chain with the beams. Since the bolts are  
15 allowed to rotate in the holes the beams are allowed to rotate as well.

sub  
B7  
The beams 18 are made from aluminium, but it could be made from any material having a good thermal conductivity. The aluminium profiles may preferably be coated with a plastic coating such as a PTFE or Teflon™ coating. The coating enables the form frozen food  
20 items easily to drop of the belt instead of sticking to the belt and further protects the aluminium from corroding. The beams are provided with a wing shaped cross sectional shape enabling a turbulence free stream of air to pass through the passage 30 between the downward oriented beams. In addition the smooth shape of the surface increases the quality and thus the value of the form frozen product further.

25

The wing formed cross sectional shape of the beams provides a top part of the beams, when raised to a horizontal position, which top part forms a platform for form freezing of the products. The products lying on the platform quickly form freezes with a plan surface towards the plan platform, both due to the cooling inducted from the beams below the  
30 products and due to the cooling from the cold air from above the products. After the from freezing the stiffness of the products hinders that the shape changes in the rest of the process when moving between the conveyors of the chamber. The very high heat convection capabilities of the aluminium beams ensures that the cooling of the products is extremely fast compared with the cooling of traditional conveyors made of plastic or made  
35 of a steel grid where consequently only the thermal convection from cold air contributes to

30 It is essential for the freezing capacity as well as for the product quality that the food products are positioned precisely and flat against the surface of the form freezing conveyor belt. Referring to Fig. 5 the in-feed conveyor belt in the in-feed unit 1 should therefore preferably be provided with an end 31, which is adapted to convey the food to a point near the surface of the form freezing conveyor belt. The conveying speed of the

35 form freezing conveyor belt should be at least as fast or even faster than the conveying

speed of the in-feed conveyor belt. In that way the food products are pulled off the in-feed conveyor belt and that minimises the risk of the food products being twisted at the transfer between the two conveyors belts.

- 5 The full freezing conveyors 3 and 4 are made of PE-plastic with half open conveyor belts and with steel side-chains made of stainless steel on each side. By using steel side-chains and conveyor belts made of plastic, a heating expansion on the plastic conveyor can be reduced. The steel side-chain hinders the expansion of the plastic conveyor and has the same heat expansion coefficient as the frame, at a position where the conveyors
- 10 are. There it is not a to heat up the chamber e.g. for the defrosting of the evaporators. By defrosting the evaporator the temperature goes from appr.  $-38^{\circ}\text{C}$  up to appr.  $30^{\circ}\text{C}$  and so there will be significant expansion of the regular plastic conveyors. This construction of the full freezing conveyors enables better glazing abilities than with the known constructions for full freezing, where glazing is performed after the product leaves the
- 15 freezer. During that procedure it may happen that the temperature of the products is lowered by the glazing so that the product loses its quality. Furthermore the products can freeze together which again lowers the price of the product.

The conveyors are driven by frequency controlled electrical gear motors which work

20 independently. On the end of these gear motors, impulse indicators are connected to sensors so that a control computer can count the pulses and therefrom calculate the location of each beam in the belt conveyor. A connected control computer, e.g. in the form of an industrial PC - not shown in the Figs. can therefore at all time track the exact loop position of the conveyors independently and therefrom regulate the system. The control of

25 the chamber may preferably be performed with a software code stored in the memory of the industrial computer.
